

Diversity in the living world

Name: Manithurica A

Grade: V

Date: 14/10/2023

Subject: Science

31
40

ditto
A Ammankuthik

I Choose the correct answer

☒ a) Fibrous roots

☒ b) All of these

☒ c) Maize

☒ d) Polluted pond with few fish

☒ e) None

☒ f) All of these

II Match the following

☒ 1 Monocot seed - One cotyledon

☒ 2 Dicot seed - Two cotyledons

☒ 3 Rhododendron - Mountain plant

☒ 4 Aquatic mammal - Whale

☒ 5 Frog - Amphibian

III Answer the given question as true or false

☒ 1 True

☒ 2 True

☒ 3 False

☒ 4 True

☒ 5 True

☒ 6 True

☒ 7 True

IV Differentiate between the following

12)

Hot desert camel	Cold desert camel
• 1 hump	• 2 humps
• Thick eye lashes	• Normal eye lashes
• Thin fur	• Thick fur
• Long legs	• Short legs

13)

Herbs	Shrubs	Trees
• Soft green stems	• Thin wood stems	• Thick wood trunk
• small	• Medium	• Large
• Medicinal value	• Some medicinal value	• Not much medicinal value

IV Answer the questions in brief

19 Rhododendrons:

They have small leaves because of the strong winds. If wind blows and they might get cut or fall but even if they fall there will still be a lot left. If there is snow fall then the snow can easily fall and not branch up at the top causing the tree to collapse.

20 Biodiversity

Biodiversity is not same in forests and deserts because there are many different animals and plants. For example take a cactus and a mango tree. They both are adapted to different conditions like in the desert it is hot so cactus have spines instead of leaves because leaves lose too much water through their stomata but mango trees have leaves and adapted to the normal conditions. Same goes for animals. Camels are adapted to the hot

different. But other animals in the forests are not and are adapted to normal conditions. This is how biodiversity differs.

1) Frogs

Frogs are adapted to both land and water because they are amphibians which means they live part of their lives in water and part in land. Because of this they are adapted to this and can swim well and also have ^{large} gills to breathe underwater.

2) Community protected forests

We should conserve community protected forests because they are vital to biodiversity. There are a lot of unique plants and animals there and they will lose their home if we don't conserve them. They also play vital roles on Earth in converting carbon dioxide into oxygen.

3) Answer the following question in detail

1) Classification of plants

I would classify plants whether they are herbs, shrubs or trees because then I can learn more things about them in the garden which would be useful to learn about their medicinal value. How does it differ from herb, shrub and tree. I would learn about their size and stems which would be useful for differentiating them. I would then learn about their differences, similarities and how unique they are, just because of this method of grouping.

2) Aquatic and terrestrial habitats

aquatic habitats and terrestrial habitats are different. They come with unique adaptations and challenges. Some of them are

that they both have predators and prey but have different
issues like different kinds of pollution and get affected
all because of us humans. In aquatic habitats there is
water pollution. In terrestrial habitats there is air pollution,
climate change and deforestation. Some animals have different
adaptations like in the water fish have gills to
breathe but mammals on land have lungs to breathe.
Underwater fish have streamlined bodies to move swiftly
while mammals on land have special hooves and
paws some to move swiftly and some to run
fast.
